Abstract
Auction-based e-commerce is an increasingly interesting domain for developing trading agents competing in multi-agent electronic markets. We present a framework for defining trading scenarios based on fish market auctions. In these scenarios, trading (buyer and seller) heterogeneous (human and software) agents of arbitrary complexity participate in e-auctions under a collection of standardized market conditions and are evaluated against their actual market performance. Such competitive situations constitute convenient problem domains in which to study issues related with agent architectures in general and agent-based trading strategies in particular. The proposed framework, FM, constitutes a test-bed for trading agents in auction tournament environments.

1 Introduction

Internet is spawning many new markets. In this sense, we observe that the proliferation of on-line auctions in the Internet such as Auctionline (http://www.auctionline.com), Onsale (http://www.onsale.com), InterAUCTION (http://www.interauction.com), eBay (http://www.eBay.com), and many others has established auctioning as a main-stream form of electronic commerce. Thus, agent-mediated auctions appear as a convenient mechanism for automated trading, due not only to the simplicity of their conventions for interaction when multi-party negotiations are involved, but also to the fact that on-line auctions may successfully reduce storage, delivery or clearing house costs in many markets. This popularity has spawned research and development in agent-mediated auction houses as well as in trading agents endowed with intelligent auction strategies.

The matter of trading within an auction house appears to be numbingly complex, because of the numerous variables coming into play. The actual conditions for deliberation are not only constantly changing and highly uncertain new goods become available, buyers come and leave, prices keep on changing; no one really knows for sure what utility functions other agents have, nor what profits might be accrued but on top of all that, deliberations are significantly time-bound. Hence there is the intricate matter of providing agent developers with some support to help them face the arduous task of designing, building, and tuning their trading agents before letting them loose in wildly competitive markets.

The FishMarket project[7] conducted at the Artificial Intelligence Research Institute (IIIA-CSIC) attempts to contribute in that direction by developing FM, an agent-mediated electronic auction house which has been evolved into a test-bed for electronic auction markets. The resulting framework, FM[1], constitutes an example of an agent-mediated electronic institution in the sense proposed in [5]. Conceived and implemented as an extension of FM96.5[3] (a
Java-based version of the Fishmark auction house, FM allows to define trading scenarios based on fish market auctions (Dutch auctions). It provides the framework wherein agent designers can perform controlled experimentation in such a way that a multitude of experimental market scenarios that we regard as tournament scenarios due to the competitive nature of the domain of varying degrees of realism and complexity can be specified, activated, and recorded; and trading (buyer and seller) heterogeneous (human and software) agents compared, tuned and evaluated. We argue that such competitive situations constitute convenient problem domains in which to study issues related with agent architectures in general and auction strategies in particular.

2 System Features

The current version of FM, FM0.9beta[4], is now available and can be downloaded from the FishMark project web page. Next, we summarize the most salient features of this very first release:

- **FM** is completely written in Java.

- The customizability of FM allows for the specification, and subsequent activation, of a large variety of market scenarios (see Figure 1): from simple toy scenarios to complex real-world scenarios, i.e., from extremely simple market scenarios in which the same auction is repeated over and over till market scenarios that make FM behave like the actual market. This capability of scenario generation allows the repeatability of the experiments (tournaments) to be conducted.

- **FM** is multi-user. It allows multiple users to spawn their agents in their own machines in order to make these to participate in remote tournaments.

- **FM** remains architecturally neutral since no particular agent architecture (or language) is assumed or provided for building trading agents. Alternatively, a library of agent templates written in Java, C, and Lisp accompanies this release in order to assist agent programmers to build their agents. In this way, the programming effort narrows down to developing auction strategies. Importantly, these templates handle the connection of the trading agent to the FM interagents: autonomous software agents which intermediate the communication between the trading agents and the institution, the market, enforcing them to follow the rules of the game[2, 6].

![Fig. 1: Tournament Parameter Settings](image)
A built-in agent builder facility allows for the automatic generation of agents with customizable auction strategies, so that families of agents capable of simulating different trading behaviours can be easily created.

Auctions can be monitored step-by-step thanks to the FM Monitoring Agent shown in Figure 2. This keeps track of every single event taking place during a tournament in order to obtain a visual, global representation of the agents’ flow from scene to scene within the market as well as the communication flow (what the agents utter and when).

The FM database stores the information to be used by trading agents to carry out market analysis and auditing.

FM has been designed to be as user-friendly as possible. Thus, the FM GUI allows the whole interaction between the users and FM to be done through graphical interfaces. For instance, Figure 3 shows the GUI employed by a human buyer to take part in a market session.

3 Future Work

But more importantly, the design and construction of FM has served to prove the usefulness of the use of organizational concepts (such as roles, groups or institutions) for the deployment of complex social structures in multi-agent systems. Thus our future work is to concentrate on the completion of a (both graphical and textual) specification language for a special type of multi-agent systems: electronic institutions. Ideally such a language shall support the automatic generation of electronic institutions as well as some of their participating agents. For instance, such a language would permit to specify an auction house in order to obtain the infrastructure (conversation protocols and interagents in the sense proposed in [2]) required for ensuring a sound multi-agent trading interaction.
3 Future Work
