Overview

Systematic Search

- Search Tree
- Backtracking (BT)
- Conflict-Directed Backjumping (CBJ)
- Dynamic Backtracking (DB)
- Heuristics

Local search

- Breakout

Search Tree

State space: explored as a tree

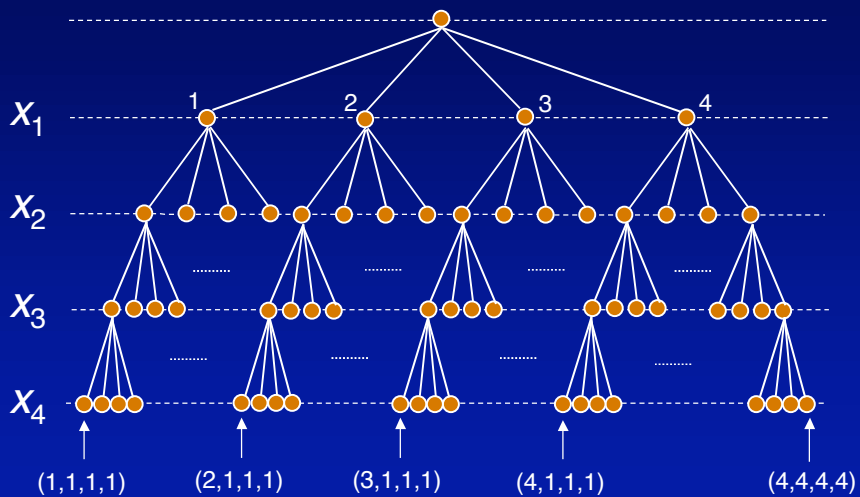

- root: empty
- one variable per level
- successors of a node:
 - one successor per value of the next level variable
 - meaning: variable x value

Tree:

- each branch defines an assignment
- depth n (number of variables)
- branching factor d (domain size)

Search tree for 4-queens

Backtracking Algorithm

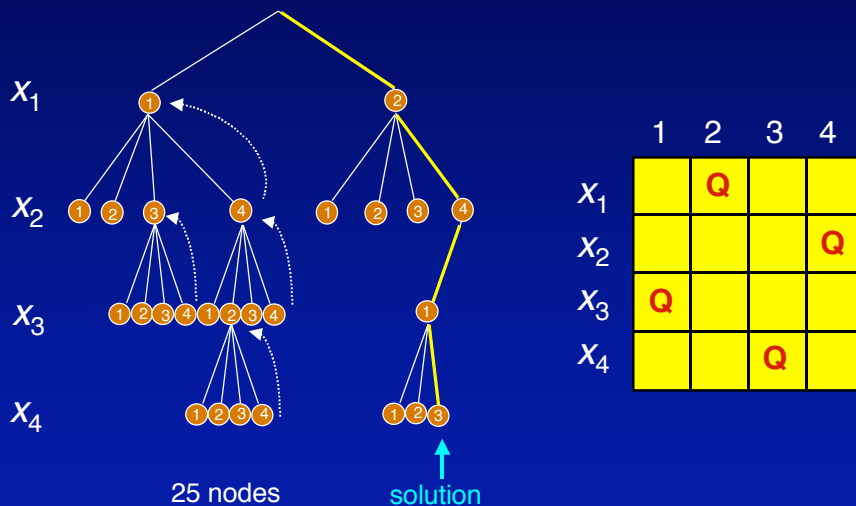

Depth-first tree traversal (DFS)

At each node:

- check every completely *assigned* constraint
- if consistent, continue DFS
- otherwise, prune current branch
- continue DFS

Complexity: $O(d^n)$

Backtracking on 4-queens

Problems of Backtracking

Thrashing:

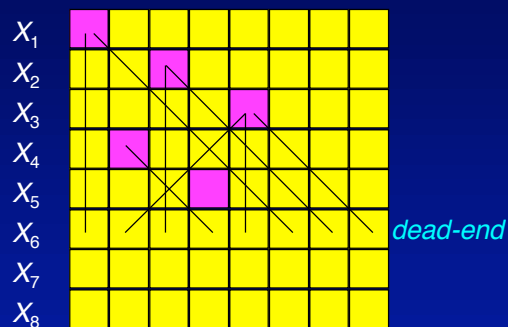

- the same failure can be rediscovered an exponential number of times

Solutions:

- check not completely assigned constraints: *propagation*
- non-chronological backtracking: *backjumping*

Non-chronological Backtracking

Changing X_5 does NOT remove the dead-end

Backtrack on a culprit variable: X_4

Conflict Set

$CS(x_k)$: assign. variables in conflict with some value of x_k

x_1										\emptyset
x_2	1	1								$\{1\}$
x_3	1	2	1	2						$\{1,2\}$
x_4	1									$\{1\}$
x_5	1	4	2							$\{1,2,4\}$
x_6	1	3	2	4	3	1	2	3		$\{1,2,3,4\}$
x_7										
x_8										

- Backtrack: jumps to the *last* variable in $CS(x_k)$

- $CS(x_k)$ is *backed-up*:

$$x_k \sqcap x_i$$

$$CS(x_j) = CS(x_j) \cup CS(x_k) - x_i$$

- x_k conflicts with var. before x_i are passed to x_j

Conflict-Directed Backjumping

Non-chronological backtracking:

- jumps to the last variable in the conflict-set
- the conflict set is backed-up
- intermediate decisions are *removed*

	1	2	3	4	
x_1	Q_1				
x_2					
x_3		Q_2			$\{x_1\}$
x_4	x_1	x_3	x_3	x_1	$\{x_1, x_3\}$

Nogoods

Nogood: subset of incompatible assignments

Example: map colouring, x_1, x_2, x_3 adjacent, $D = \{a, b\}$

$$(x_1 = a \wedge x_3 = a) \quad \text{or equivalently}$$

$$\boxed{\text{lhs}} \quad x_1 = a \wedge x_3 \neq a \quad \boxed{\text{rhs}}$$

Nogood resolution:

$$\left. \begin{array}{l} x_1 = a \wedge x_3 \neq a \\ x_2 = b \wedge x_3 \neq b \end{array} \right\} \quad x_1 = a \wedge x_2 \neq b$$

last variable in lhs

Dynamic Backtracking

Non-chronological backtracking:

- one nogood per each incompatible value
- empty domain: new *ng* by nogood resolution
- backtrack to the variable in *rhs(ng)*

	1	2	3	4
x_1	Q_1			
x_2				Q_3
x_3		Q_2		
x_4	$x_1=1$	$x_3=2$	$x_3=2$	$x_1=1$

$$\begin{array}{l} x_1=1 \wedge x_4 \neq 1 \\ x_3=2 \wedge x_4 \neq 2 \\ x_3=2 \wedge x_4 \neq 3 \\ x_1=1 \wedge x_4 \neq 4 \end{array}$$

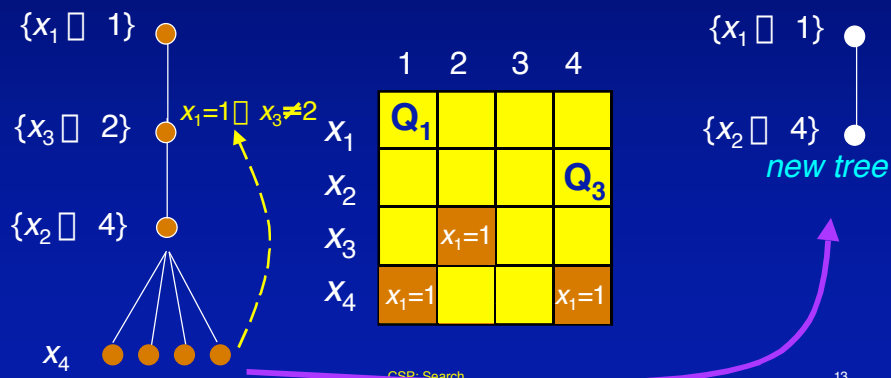

$$\boxed{\text{ng: } x_1=1 \wedge x_3 \neq 2}$$

Dynamic Backtracking (II)

Non-chronological backtracking:

- jumps to the last decision *responsible* for the dead-end
- intermediate decisions are *NOT* removed

13

Variable Ordering

Static variable ordering: variable associated with level

Dynamic variable ordering:

- each branch considers all vars / different ordering per branch

14

Variable Selection

Node q , what is the next variable to assign?

1. There is a solution in $\text{succ}(q)$: *any var is fine*
2. There is no solution in $\text{succ}(q)$: *assign var that sooner detects that there is no solution*

What is more often?

- Except trivial problems, case 2
- *Biggest effort*: escaping from problems without sol.

Fail-first: first the variable that sooner detects failure

Heuristics

Min-domain:

- First the variable with less compatible values with the current partial solution
- Minimize the search tree

Max-degree:

- First the variable involved in more constraints
- Maximize constraint propagation

Combination:

- First the variable with min domain/degree
